

Pixel Circuit For Liquid Crystal Display Using Static Memory

BACKGROUND OF THE INVENTION

1. Field of the Invention

5 The invention is related to a Pixel Circuit For Liquid Crystal Display Using Static Memory, wherein a digital circuit is installed at a pixel of the liquid crystal display for processing static image. The digital circuit works with an analogue—analog circuit for lowering the power 10 consumption so as to accomplish power saving function of a Pixel Circuit For Liquid Crystal Display Using Static Memory.

2. Description of the Prior Art

Liquid crystal display (LCD) is widely used in 15 notebook computers and various apparatus with display functions. An image pixel driving circuit used in the LCD is an analogue—analog circuit. Among prior art LCD elements, passive or active matrix liquid crystals such as thin film transistor (TFT) and twisted nematic (TN) are 20 used. A schematic view of exemplary circuit of a prior art pixel circuit is shown in the FIG. 1. The circuit shown in the FIG. 1 is used as a basic unit to form a LCD. All unit circuits share a scanning line 103 and data line 105. FIG.

Group Art Unit 2673

1 shows a circuit of active matrix TFT LCD 101. The architecture of image pixel is composed of TFT LCD 101, a capacitor 107 a liquid crystal unit 109. An analogue analog voltage is required to write into the capacitor 107
5 so as to display gray level image, and a scanning line 103 as the circuit switch. When a signal from scanning line 103 indicates to switch the liquid crystal unit on, the data line 105 then charges/discharges the capacitor 107. Due to the malfunction of TFT 101, a current leakage may occur
10 and result in gray level loss. To prevent aforementioned phenomenon and render a good gray level display, the data line 105 is required to continually charge/discharge TFT 101. Said operation results in a refresh rate data, which serves as an important reference for LCD performance.

15 In the prior art, a surface stabilized ferroelectric liquid crystal (SSFLC) is also used to form a LCD. The SSFLC has spontaneous polarization. When an external electric field is applied, the direction of the spontaneous polarization reverses and such direction is then retained.
20 As a result, when the LCD displays static image, it's no longer required to continually writing signals into pixels, neither is required to continually charge/discharge data

line, so as to reduce power consumption. The drawback of the method is that such display only shows black and white. A gray level display requires complicated circuits such as pulse width modulation (PWM).

5 In order to resolve the aforementioned drawbacks of Pixel Circuit For Liquid Crystal Display Using Static Memory such as high power consumption or requirements to use complicated circuits, a digital circuit is employed at a pixel of the LCD in the present invention, such frequent
10 display refresh is eliminated and the power consumption is reduced.

SUMMARY OF THE INVENTION

The invention is about a Pixel Circuit For Liquid Crystal Display Using Static Memory. A digital circuit is installed at a pixel of the liquid crystal display for processing static image. The digital circuit works with an analogue—analog circuit for processing dynamic image. Traditionally, analogue—analog pixels have better performance for gray level display. According to the
15 present invention, a digital operation is provided, wherein the data line is not required to be charged/discharged, such that the power consumption is reduced. In addition,

several multiplexers are provided to enhance the digital and ~~analogue~~ analog signal processing, for lowering the power consumption so as to accomplish power saving function of a Pixel Circuit For Liquid Crystal Display

5 Using Static Memory.

The Pixel Circuit For Liquid Crystal Display Using Static Memory comprises a plurality of multiplexers, acting as switching elements for performing a plurality of output voltage transforming functions; a static memory, 10 connecting to a scanning line, a thin film transistor and a capacitor, for storing the digital voltage signals stored in the capacitor; a thin film transistor, for connecting a scanning line and a data line, acting as a control switch of the circuit; and a capacitor, connecting to the thin film 15 transistor, where ~~analogue~~ analog or digital signals from the data line are stored.

The invention can be more fully understood by reading the following detailed description of the preferred embodiments, with reference made to the accompanying 20 drawings.

**DETAILED DESCRIPTION OF THE PREFERRED
EMBODIMENTS**

5 The present invention initializes a digital operation mode of static memory (SRAM) to enable a static image display without continually refreshing the display, so as to reduce power consumption and save power.

Refer to FIG. 2A, which is a block diagram showing
10 a static random access memory pixel circuit according to the Pixel Circuit For Liquid Crystal Display Using Static Memory in the third embodiment of the present invention. After the write enable function of SRAM 211 is initiated by the scanning line 203, digital voltage values from the
15 data line 205 are stored to the capacitor 207 via TFT 201. The voltage value stored in the capacitor 207 is also simultaneously written onto SRAM 211, and output from general voltage terminal Vcom or reference voltage terminal Vref depending on which is selected by the
20 multiplexer 202. Then the mode control terminal 206 controls the second multiplexer 204, for determining whether to operate on the digital mode, where Vcom or

Group Art Unit 2673

Vref from the first multiplexer 202 is used to apply a bias on liquid crystal unit 209, or operate in the analogue analog mode, where the analogue-analog voltage image value stored in the capacitor 207 is used to apply a bias on 5 liquid crystal unit 209. If the mode control terminal receives control signals for a dynamic or static image, the operation is on the first mode. The analogue-analog mode control signals are input into the second multiplexer 204 via selection terminal sel, the first mode terminal in0 may 10 connect to the capacitor 207 or connect scanning line 203 and data line 205 via TFT 201. When the scanning line 203 switches on the TFT 201, an analogue-analog image voltage value from the data line 205 is written to the capacitor 107 via the TFT 201. Then the analogue-analog 15 image voltage value is connected to the liquid crystal unit 109 via the output terminal out of the second multiplexer 204. When the operation is in the analogue-analog mode circuit for dynamic image display, such analogue-analog value and the bias of general voltage terminal Vcom from 20 both ends of liquid crystal unit 209, form the gray level display.

If the mode control terminal 206 receives digital

Examiner M. Said
Group Art Unit 2673

mode control signals for a static image, it indicates that the operation is on the second mode according to the present invention, the digital mode control signals are input into second multiplexer 204 via selection terminal 5 sel, then connected to the first multiplexer 202 via the second mode terminal in1. On the other hand, after the scanning line 203 initiates the write enable function of TFT 201 and SRAM 211, the data line 205 writes the digital voltage signals into the capacitor 207 via the TFT 10 201. the digital voltage values stored in the SRAM 211 are used for determining whether the operation should switch to general voltage terminal Vcom or reference voltage terminal Vref in the first multiplexer 202. Also, stored digital voltage value in the SRAM 211 is updated until the 15 scanning line 203 initiates the data write enable function of the SRAM 211 again. As a result, the data line 205 is not required to charge/discharge capacitor 207. The first multiplexer 202 can directly retrieve the digital voltage signals stored in the SRAM 211, then the first multiplexer 20 20 determines to operate via the general voltage terminal Vcom or the reference voltage terminal Vref, and applies a bias to the liquid crystal unit 209 via second multiplexer 204 to accomplish a bright/dim display. The worries about

current leakage of TFT 201 or capacitor 207 and the resulting digital voltage level loss are therefore waived. Such application does not only reduce the power consumption, also it is made possible to change the bias 5 status of the liquid crystal unit 209 via the general voltage terminal Vcom and the reference voltage terminal Vref.

FIG. 2B is a schematic diagram showing a static random access memory pixel circuit according to the Pixel Circuit For Liquid Crystal Display Using Static Memory 10 in the third embodiment of the present invention. According to the diagram, the second multiplexer 204 is used for switching between the first mode (analogue analog mode) and the second mode (digital mode) via using a plurality of transistors as switches. The first 15 multiplexer 202 composed of a plurality of transistors is used for switching between the general voltage terminal Vcom and the reference voltage terminal Vref. Then digital control signals for voltage switching are stored in the SRAM 211. The SRAM 211 is a circuit loop composed 20 of one or a plurality of switch transistors and inverters, for initiating data write enable function and storing the voltage signals.

FIG. 2C describes the implementation of SRAM 211. When the scanning line 203 is required to write data into SRAM 211, the data write enable (w.e.) function has to be initiated first, such that the stored digital voltage value is 5 updated. The SRAM 211 allows signals input from scanning line 203 at a write enable control terminal 401. The voltage values are memorized by delay circuit latch composed of a plurality of inverters.

FIG. 3A is a block diagram showing a static random 10 access memory pixel circuit according to the Pixel Circuit For Liquid Crystal Display Using Static Memory in the fourth embodiment of the present invention. As shown in the diagram, such Pixel Circuit For Liquid Crystal Display Using Static Memory comprises a demultiplexer 300 15 composed of a plurality of transistors, a SRAM 211, a first multiplexer 202 and a second switch device 303. The first multiplexer 202 and the demultiplexer 300 are switch elements used for switching signal input source. When the signals from the scanning line 203 switches on the liquid 20 crystal circuit, on signals are input to the TFT 201, through the TFT 201, analogue-analog voltage signals from data line 205 are input into the demultiplexer 300 at

Group Art Unit 2673

the input terminal of the demultiplexer 300. The demultiplexer 300 composed of a plurality of transistors is a device having a plurality of switch functions. If the mode control terminal 206 receives analogue-analog 5 control signals for a dynamic or static image, the operation is on the first mode. The control signals are input into the demultiplexer 300 at the selection terminal of the demultiplexer 300 via a first signal line 301. The signals for the first mode are input to second switch device 303 via second signal line 302. The second switch device 303 isolates the digital circuit from the analogue-analog circuit. The control signal of the first mode is an analogue-analog control signal. The analogue-analog control signal is input into demultiplexer 300 at the input 10 terminal via the TFT 201. The analogue-analog voltage signal from the data line 205 connected is output at the first mode output terminal out0. Since the control signal for the first mode via the second signal line 302 is an off signal to the second switch device 303, the analogue-analog 15 voltage value is output at the first mode output terminal out0 and then directly input to the capacitor 207 for applying a bias on liquid crystal unit 209 so as to 20 display a gray level image. The circuit under the analogue

analog mode uses the second switch device for isolating the SRAM 211 and the first multiplexer 202, so as to prevent the function of digital circuit and the switching of multiplexers from affected by the analogue analog voltage
5 when the operation is on the analogue analog circuit mode for dynamic image display.

In addition, when the signals from the scanning line 203 switches on the liquid crystal circuit, the on signal is input to the TFT 201 and write enable control terminal
10 401 of the SRAM 211. Through the TFT 201, the digital voltage signal from data line 205 is input into the demultiplexer 300 at the input terminal in of the demultiplexer 300. If the mode control terminal 206 receives the digital mode control signal for a static image,
15 the operation is on the second mode. The control signal from the first signal line 301 is input into a demultiplexer 200 at the selection terminal sel. In addition, the control signal of the second mode is input to the second switch device 303 via second signal line 302. The control signal
20 of the second mode is a digital control signal. The digital control signal is input into demultiplexer 300 at the input terminal via the TFT 201. The digital voltage signal from

Group Art Unit 2673

the data line 205 connected is output at the second mode output terminal out1 to the SRAM 211. The digital value stored in the SRAM 211 is used for determining whether the output terminal out of the first multiplexer 202 should 5 be the general voltage terminal Vcom or the reference voltage terminal Vref. When the second switch device 303 receives the control signal for second mode from the second signal line 302 of the mode control terminal 206 and is switched on, then the capacitor 207 connects to the 10 output terminal out of the first multiplexer 202 and the bright/dim display status of the liquid crystal unit 209 is determined based on the voltage difference between two terminals of the capacitor 207. One terminal of the liquid crystal unit 209 is the general voltage terminal Vcom', 15 and the voltage of the other terminal is the voltage of the general voltage terminal Vcom or the reference voltage terminal Vref. Due to the application of SRAM 211, the data line 205 is not required to charge/discharge capacitor 207. The stored digital voltage value in the SRAM 211 is 20 updated until the scanning line 203 initiates the data write enable function of the SRAM 211 again.

The schematic diagram in the FIG. 3B illustrates an

implementation of an embodiment according to the block diagram shown in the FIG. 3A. The first multiplexer 202 is composed of plurality of transistors acting as switches for switching between the general voltage terminal Vcom 5 and the reference voltage terminal Vref so as to determining the bright/dim display status of liquid crystal unit 209. The demultiplexer 300 composed of a plurality of transistors is a device having a plurality of switch functions. The SRAM 211 allows signals input from 10 scanning line 203 at a write enable control terminal 401. The delay circuit latch composed of a plurality of inverters memorizes the voltage value, as a reference data to mode switching of the first multiplexer 202 and the demultiplexer 300.

15 The above provides a detailed description of the embodiments according to the Pixel Circuit For Liquid Crystal Display Using Static Memory in the present invention. The present invention lowers the refresh rate of the display and the power consumption by implementing a 20 plurality of multiplexers and analogue-analog and digital pixel circuits for liquid crystal display composed of DRAM or SRAM.

Abstract

A Pixel Circuit For Liquid Crystal Display Using Static Memory is disclosed, wherein a digital circuit is installed at a pixel of the liquid crystal display (LCD) for processing static image. The digital circuit works with an analogue-analog circuit for processing dynamic image. Several multiplexers and static memory are provided to enhance the digital and analogue-analog signal processing, for lowering the power consumption so as to accomplish power saving function of a Pixel Circuit For Liquid Crystal Display Using Static Memory.
